A Patient’s Guide to 4D Brachytherapy

Professor Stephen Langley
Dr Robert Laing
Dr Julian Money-Kyrle
Dr Sara Khaksar

Tailoring Technology to Treatment
This is a booklet for men who are either considering treatment, or are being treated, for prostate cancer with brachytherapy. It also provides useful advice and information for their families. It is best read in conjunction with the more general booklet in this series, *A Patient’s Guide to Prostate Cancer*, which provides an overview of the subject and introduces terms used in this booklet. This booklet may have already been given to you, or it may be viewed and downloaded from the website: www.prostatebrachytherapycentre.com

Professor Stephen Langley and Dr Robert Laing are retained clinical advisors and shareholders in BXTAccelyon Ltd, a private company involved in the provision of seeds for prostate brachytherapy treatment. The clinician treating you may make use of BXTAccelyon’s services.

**Introduction**

**Brachytherapy** is a technique for treating prostate cancer, using tiny radioactive seeds of Iodine-125 \(^{125}\text{I}\) that are inserted permanently into the prostate gland. ‘Brachy’ means close and, in this treatment, the radioactivity is inserted directly into the cancerous organ. This is unlike conventional external beam radiotherapy, where it travels through the body tissues before reaching the prostate gland. Brachytherapy provides a higher, more localised radiation close to the prostate and minimises the effects on the surrounding tissues, such as the rectum and bladder.
The seeds are tiny canisters of Titanium (4.5mm long by 0.8mm diameter) which contain the radioactive isotope Iodine-125. The half-life of radioactive Iodine-125 is approximately 60 days, which means that most of the radiation is released from the seeds into the prostate gland over the first 3 months. They continue to be biologically active for about 9 months in total. After that, they become effectively inactive.

The latest techniques for brachytherapy were developed in the mid-1980s with the arrival of sophisticated ultrasound probes. These devices enable the accurate implantation of seeds into the prostate, allowing high doses of radiation to be delivered to the cancerous gland.

There are now long-term results from patients who were treated up to 20 years ago, which show that this form of treatment is highly effective in treating and curing patients with early prostate cancer.

Brachytherapy appears to be as effective as other conventional treatments, such as surgery (radical prostatectomy) or external beam radiotherapy, but with a lower side-effect profile (see Table 1).

However, brachytherapy is not the only effective treatment for prostate cancer and some patients may be better suited by other methods of treating their prostate cancer.

**Patient selection**

Patients ideally suited for brachytherapy are those for whom there is a good chance that their cancer is confined to the prostate and has not spread outside of the gland. Occasionally, where it is thought there is a higher likelihood that the prostate cancer may have spread to the tissues surrounding the gland, patients will be offered a shortened five-week course of external beam radiotherapy prior to undergoing a brachytherapy implant. This combination therapy allows a greater margin of tissue around the prostate to be treated.

For more information on radiotherapy, please read *A Patient’s Guide to External Beam Radiotherapy*, which should be available at your hospital or may be viewed and downloaded from the internet at: www.prostatebrachytherapycentre.com

The brachytherapy team will advise you whether your prostate cancer is suitable for treatment by brachytherapy. Suitable patients will normally have the following characteristics:

- The PSA (Prostate-Specific Antigen) level should ideally be less than 25ng/ml at the time of their diagnosis.

- The *stage* of the cancer should be either T1 or T2 on rectal examination, indicating a prostate cancer confined to the gland.
The **grade** of the cancer should ideally be a Gleason score of 8 out of 10 or less.

Patients should not suffer with severe urinary symptoms, such as a very weak stream or difficulty emptying their bladder. Occasionally, a small prostate operation (‘limited’ TURP [transurethral resection of the prostate]) may be performed to unblock the urinary system, before the implant is performed (see *A Patient’s Guide to TURP*, which should be available at your hospital or may be viewed and downloaded from the internet at: www.prostatebrachytherapycentre.com).

Ideally, the prostate should be relatively small – less than 60cc. If the gland is too large, areas of the prostate may be shielded by the bony skeleton, preventing an adequate irradiation of the whole gland.
adequate implant being performed. In this case, patients are given a 3-month course of hormone therapy to shrink the prostate down to a size that will allow implantation.

- Patients who have had previous prostate surgery, such as a conventional TURP, are usually best treated by an alternative therapy (e.g. radical prostatectomy or conformal external beam radiotherapy).

**Transrectal ultrasound, showing a series of prostate ultrasound images used to construct a 3-dimensional image of the prostate (volume study) and treatment plan.**

*Key: red line = prostate; blue line = limit of radiation to be delivered.*
The assessment visit

Once referred to the brachytherapy team for assessment as to your suitability for this treatment option for your prostate cancer, you will be sent an outpatient appointment, along with this booklet and an information video.

At your outpatient visit, you may see many members of the brachytherapy team, including a Consultant Urologist and/or a Consultant Oncologist.

A general history will be taken as to previous illnesses, operations, medication, etc.

You will have a rectal examination carried out to assess the stage of the cancer. You will also undergo a painless transrectal ultrasound (TRUS) to assess the size and shape of the prostate.

You will be asked to complete a short questionnaire (see pages 20 and 21) to assess your urinary symptoms and to come to the clinic with a comfortably full bladder. This is because a flow rate and bladder scan to measure the residual volume of urine left behind after voiding will be performed.

Discussion of the stage and grade of your cancer will take place, as well as your suitability for prostate brachytherapy.

Following your visit, if you are suitable for brachytherapy and are happy to proceed with this as a treatment option for your prostate cancer, the Brachytherapy Co-ordinator will then be able to schedule your potential dates.
The Procedure

Prostate brachytherapy is now usually carried out as a one-stage real-time brachytherapy technique called 4D Brachytherapy. This technique not only allows for improved accuracy of the seed placement (so delivering the optimal radiation dose to the prostate) but also it can be done in a time-efficient manner. This allows a quicker recovery for the patient following the procedure.

An ultrasound of the prostate to accurately assess the size and shape of the gland will normally have been performed in clinic at the time of the initial assessment. This information will allow us to order the specific number of seeds needed for the implant. Occasionally, patients require a period of hormone therapy before their brachytherapy, which will shrink the prostate size down. In this situation, a new ultrasound assessment will be performed approximately 3 weeks before the procedure to measure the new size of the gland.

Very occasionally, we may wish to perform the volume assessment under a general anaesthetic as a day-case procedure. This enables us to assess whether the pelvic skeleton will allow adequate access to a large prostate gland for the implant, when doubt exists from the clinical assessment.

The 4D Brachytherapy implant will usually be performed at least 3 weeks after the clinical assessment. This is due to the time required to calculate the number of radioactive seeds needed, which are prepared in the USA and then sent to us for implantation on a specific date.

The day before the implant, you will need to have bowel preparation, to ensure that the rectum is empty, so that clear ultrasound images of the prostate can be obtained. You will
be sent a sachet of Picolax powder to mix with water and to drink the day before. It is important that you drink plenty of water both the day before and for 48 hours afterwards to re-hydrate yourself.

You will be admitted on the day of the implant. The procedure is performed under a general anaesthetic in the operating theatre. Radioactive Iodine-125 seeds are inserted into the prostate under transrectal ultrasound guidance, using needles that pass through the skin between the legs behind the scrotum (the perineum).

Each needle may deliver between 2-6 seeds and, normally, 20-30 needles are required to deliver between 60-120 seeds in total. The seeds implanted around the edge of the prostate are woven into a strand of absorbable material to help maintain their position.

Using the planning computer in the operating theatre, we can accurately determine where to implant the seeds within the centre of the gland. These seeds are implanted individually, rather than in strands, to maximise our ability to tailor the treatment to the prostate shape. This latest technique allows us to optimise the radiation dose to the prostate whilst minimising the dose received to the surrounding tissues and so reduce any side-effects.

A catheter is placed into the urethra once you are under anaesthetic. This remains in place until after the CT scan and the effects of the anaesthetic have fully worn off. X-rays are taken throughout the procedure, to check the position of the seeds.
Catheter in urethra

Needle, delivering seeds into prostate

Template to aid accurate placement of the needles delivering the seeds

Ultrasound probe in rectum for needle guidance

Surgeon’s view of the implantation process.

Seed/needle preparation.
CT scan
You will have a CT scan either directly following your implant, or early the following morning. This procedure will allow us to check the position of the seeds, to ensure
that an adequate radiation dose has been delivered and it is also an essential part of the ongoing audit process of our brachytherapy programme.

Your catheter will be removed once you have had your CT scan.

Post-Operative Side-Effects

Immediate

Immediately after the operation, you may notice some bruising beneath the scrotum and tenderness between the legs. You will have an ice bag placed between your legs whilst in the recovery room, to help reduce this bruising and discomfort.

Once the catheter has been removed, you may notice some discomfort when passing urine. While in hospital, your urine will be filtered, to ensure that any loose seeds that you may pass are caught. This event is rare and usually will happen within the first 24 hours following implant.

We will ensure that you are able to pass urine satisfactorily before you are discharged home.

A small percentage of patients (approximately 2%) may hold a significant residual amount of urine in their bladder immediately after the implant. This may result in either requiring a catheter to be left in place for a week, or patients being taught how to pass a fine catheter themselves for a period of time. This is normally only for two weeks or less, until normal voiding returns.

It is quite common to see some blood in the urine for a
day or two after the procedure. This is quite normal, so do not be alarmed.

**Advice on drinking**

For one week after the implant, you are encouraged to drink plenty of water to flush through any small blood clots that may develop out of the bladder. Thereafter, you should return to a normal drinking pattern and your daily intake should not normally exceed 1.5 litres per day.

It is important that you avoid all caffeinated drinks (tea, coffee, coke) in the first few months after the implant, as these are likely to aggravate your urinary symptoms. We would ask that you also avoid the decaffeinated varieties, as they do contain some caffeine.

*Caffeine-free* drinks are ideal and many of our patients choose to drink Red Bush Tea as a caffeine-free alternative.

Alcohol, however, in moderation, is fine. You may also find that cranberry juice is helpful. 1-2 glasses per day is enough.
Urinary symptoms

After the implant, it is common for patients to notice a gradual worsening of their urinary symptoms. Often, patients will find that they do not have too many problems during the first couple of weeks following implant. Symptoms will then peak at around 4-6 weeks post-implant, but improve over the ensuing months. For this reason, we would normally advise that you do not travel outside of the UK for the first 2-4 weeks following the implant.

Typically, patients complain of a slow stream, with urinary frequency and urgency during the day and night. There may also be a feeling of incomplete emptying of the bladder, with the need to strain. Most often, the symptoms are worse at night and during periods of inactivity.

These side-effects are due to the swelling of the prostate following the procedure and irritation of the prostate and bladder lining due to radiation from the seeds. They are temporary and will settle in time.

We would normally expect that by 6-9 months following implant a patient’s urinary symptoms will have returned to how they were before treatment began.
Medications
After the brachytherapy implant, all patients will receive:
- An alpha-blocker, such as tamsulosin (Flomax®) or alfuzosin (Xatral®).
- An anti-inflammatory painkiller, such as diclofenac sodium (Voltarol®).
- A course of antibiotics, usually ciprofloxacin, for one week.
- A supply of a laxative, such as Senna.

Alpha-blocker
This tablet relaxes the muscle within the prostate gland and helps to reduce the narrowing of the water pipe as it runs through the swollen prostate, so minimising urinary symptoms. This is best taken in the early evening.
You will be encouraged to take this tablet for at least 3-6 months after the implant and you should get a repeat prescription from your GP.

Anti-inflammatory painkiller
This tablet has two benefits. It is an effective painkiller and is also useful in reducing the inflammation from the swollen prostate gland, so helping to relieve urinary symptoms. You will receive a one-week supply of this tablet from the hospital. Some patients find that they may require a longer course of this medication and this can usually be obtained from your GP.

Antibiotic
You will receive a one-week course of antibiotics, such as ciprofloxacin. These will help to prevent infection following the implant. They are safe to take with an alcoholic drink if desired.

Urinary retention
As previously mentioned, approximately 1 in 50 patients may have temporary difficulty in emptying their bladder after the implant and this can result in urinary retention.
The symptoms of urinary retention are an inability to pass urine and lower abdominal discomfort, usually with a constant desire to urinate. Should this occur, we suggest that you either contact us (via the number at the back of this booklet) or, in a painful emergency situation, it may be necessary to contact your GP or local A & E department.

In the first instance, you will merely need to have a catheter inserted into your bladder to drain the retained urine. Normally, however, we do prefer to teach patients to catheterise themselves, using single-use disposable catheters, which most patients find is easier and more convenient. This avoids having a permanent, indwelling catheter. The inability to pass urine is usually transient and, within a few weeks, you will find that your bladder starts to empty properly again and the need for catheterisation will stop.

**Bowels**

Some patients find that, immediately following the implant, their bowels tend towards constipation. This can usually be relieved by an increase in fresh fruit, vegetables and fibre. Also recommended is a daily tablet of Senna.

Occasionally, patients can experience troublesome rectal symptoms following their implant, such as frequency of opening their bowels or diarrhoea. This symptom is more common following additional external beam radiotherapy than with a brachytherapy implant alone. The symptoms are usually self-limiting and can often be helped by Normacol®, a dietary fibre supplement best taken each morning with cereal. Very occasionally, steroid suppositories are required. These symptoms tend to start 6 months after the implant.

**Erectile dysfunction**

Erection of the penis may be affected by brachytherapy. The risk is lower in younger men who have had no previous difficulties obtaining an erection and it tends to affect about 20% of our patients following treatment.
Current research suggests that the risk is lower than with other treatments, such as radical prostatectomy. Treatment with tablets, such as Viagra, is usually effective in approximately 80% of patients, should difficulties in achieving and sustaining an erection occur.

Some men notice a decreased or dry ejaculate following brachytherapy. This is a common, temporary, side-effect of Flomax, but can also occur as a result of the brachytherapy implant itself.

**Follow-up after brachytherapy**
Patients will be regularly reviewed in clinic and their PSA will be first checked 3 months after the implant. Usually, it will then be checked every 3 months for the first year and every 6 months thereafter. Approximately 25% of patients will experience a temporary small rise in PSA (a ‘PSA bounce’), typically anywhere between 6 months-2 years after the procedure. This is quite common, with the PSA dropping again after a few months. The reasons for this bounce phenomenon are unclear, but it does not have any effect on the overall success of the treatment.

**Other Information**

**Resuming normal physical activities**
You should be able to resume normal activities (e.g. work, shopping) within a few days. However, we would normally advise you to avoid heavy lifting or strenuous activity for the first two weeks after your implant. Many patients are concerned about whether an implant poses any potential dangers of radiation exposure to their family and friends. It is important to remember that although the seeds are radioactive, you
are not. Objects that you touch or items that you use do not become radioactive. Other people may use linen, clothing, tableware, or dishes after you without special precautions. Your bodily waste (urine and stool) are not radioactive.

There are no restrictions on travel or physical contact with other adults. However, special precautions listed below should be taken when in contact with small children and pregnant women in the first 2 months following treatment.

**Family relations**

You may sleep in the same bed as your partner, provided she is not pregnant. Sexual intercourse, using a condom, may be resumed after 1 month, once you feel comfortable to do so. Initially, a condom should be used, because there is a very small risk that a seed may be passed in the semen.

Your semen may be discoloured dark brown or black. This is normal and is a result of bleeding that may have occurred during the implant. Following 2-3 ejaculations, it will not be necessary to use a condom.

**Radiation protection**

There are no formal restrictions on your activities when you return home. However, we recommend that the following precautions are followed for the first 2 months after the implant, after which time the radiation levels reduce significantly and you may resume life as normal.

1. Women who are or may be pregnant should not sit very close to you (e.g. on the same sofa or bed) for more than a few minutes a day. However, you may continue to greet or hug them as you would have done before the implant and spend as long as you wish in the same room as them.

2. Do not sit children on your lap for long periods. As
explained above, you may briefly cuddle them for a few minutes and they may stay in the same room as you for as long as you wish.

3. Other adult family, friends and colleagues are not at risk and restrictions on time and activities are not necessary.

**What happens if the cancer returns?**
Whilst the success rate of brachytherapy seems to be as high as for surgery, neither treatment option can guarantee cure. Should the cancer return in the prostate gland, a radical prostatectomy, cryotherapy or high-intensity focused ultrasound (HIFU) are possible further treatment options that can still provide cure.

**Summary**

4D Brachytherapy is a very effective treatment for early prostate cancer, with patients rapidly returning to normal activities.

Urinary incontinence after this procedure is rare (less than 1%) and the risk of impotence seems much lower than with surgery and external beam radiotherapy.

Patients do, however, experience a temporary deterioration in their urinary symptoms for the first 6 months or so after their implant.

It is important to remember that the day you are discharged from hospital after the implant is really the day that your radiotherapy treatment starts.

These questions are designed to assess your ease of urination.

1. **Incomplete Emptying** Over the past month, **how often** have you had a sensation of not emptying your bladder completely?
   - Not at all
   - Less than 1 time in 5
   - Less than half the time
   - About half the time
   - More than half the time
   - Almost always

2. **Frequency** Over the past month, **how often** have you had to urinate again less than 2 hours after you finished urinating?
   - Not at all
   - Less than 1 time in 5
   - Less than half the time
   - About half the time
   - More than half the time
   - Almost always

3. **Intermittency** Over the past month, **how often** have you found you had stopped and started again several times when you urinated?
   - Not at all
   - Less than 1 time in 5
   - Less than half the time
   - About half the time
   - More than half the time
   - Almost always

4. **Urgency** Over the past month, **how often** have you found it difficult to postpone urination?
   - Not at all
   - Less than 1 time in 5
   - Less than half the time
   - About half the time
   - More than half the time
   - Almost always

5. **Weak Stream** Over the past month, **how often** have you had a weak urinary stream?
   - Not at all
   - Less than 1 time in 5
   - Less than half the time
   - About half the time
   - More than half the time
   - Almost always

6. **Straining** Over the past month, **how often** have you had to push or strain to start or complete urination?
   - Not at all
   - Less than 1 time in 5
   - Less than half the time
   - About half the time
   - More than half the time
   - Almost always

These questions are designed to assess whether you are experiencing erectile dysfunction or impotence. Tick the response that best describes your own situation.

1. **Could you get an erection sufficient for intercourse?**
   - Yes
   - No

2. **Are you currently taking Viagra, Levitra or Cialis?**
   - Yes
   - No

3. **Over the past month, how do you rate your confidence that you can get and keep your erection?**
   - Very low
   - Low
   - Moderate
   - High
   - Very high

4. **Over the past month, when you had erections with sexual stimulation, **how often** were your erections hard enough for penetration?**
   - No sexual activity
   - Almost never or never
   - A few times (much less than half the time)
   - Sometimes (about half the time)
   - Most times (much more than half the time)
   - Almost always or always

5. **Over the past month, during sexual intercourse, **how often** were you able to maintain your erection after you had penetrated (entered) your partner?**
   - Did not
   - Almost never
   - A few times
   - Sometimes
   - Most times
   - Almost always or always

**PLEASE COMPLETE THIS QUESTIONNAIRE FOR THE PAST MONTH**

**MALE HEALTH INVENTORY**

- Quite a bit
- Very much
- Almost always
Prostate brachytherapy: questions to ask your doctor

- Will I be given hormone treatment prior to brachytherapy? If yes, why? If not, why not?
- How long does the procedure take?
- How many of these procedures do you do a year?
- Will I require external beam radiotherapy as well as brachytherapy?
- In your experience, how successful is this procedure?
- What are your results in respect of impotence and incontinence?
- How long will I be in hospital?
- Will I have much pain after the implant?
- How soon is my follow-up appointment after discharge, and when will the PSA first be measured?
- How often will my PSA be checked?
- What should the PSA be after brachytherapy? What would it mean if it doesn’t reach that level? What would you do then?
The steps in your treatment for prostate cancer

A

Prostate Biopsy confirms prostate cancer. You are referred for a brachytherapy (BXT) assessment

Assessment by brachytherapy team and ultrasound scan of prostate in clinic

If unsuitable

If suitable

B

Possible ‘limited’ TURP 10 weeks before BXT

Possible additional external beam radiotherapy, daily for 2½ weeks before BXT

BXT; Real time implantation of seeds

CT scan to confirm seed position in prostate gland

Discharge home, same or following day

Other more appropriate treatment

C

Outpatient Appointments
First at 3 months
First PSA check at 3-4 months
